# IP ADDRESS AND ASN CERTIFICATION TO IMPROVE ROUTING SECURITY

George Michaelson APNIC R&D  
[ggm@apnic.net](mailto:ggm@apnic.net)

# Overview

- The problem with Internet routing security
- What is Resource Certification?
  - Definition
  - How it works
  - Potential use
- How Resource Certificates can be used to secure routing
  - Signing routing attestations
  - Digital signature validation with resource certificates
- Conclusion
- Q & A

# INTERNET ROUTING SECURITY PROBLEM

# Why is routing security important to you?

- Routing was built on 'trust' models
  - My network trusts your network to exchange traffic
  - Not much verification/validation other than checking whois and routing registries
- Corrupting the routers' forwarding tables can result in
  - Misdirecting traffic (subversion, denial of service, traffic inspection, passing off)
  - Dropping traffic/network isolation
  - Adding false addresses into the routing system
- You have a responsibility
  - Business now conduct more and more transactions online
  - Your clients need your protection

## Six worst Internet routing attacks

How YouTube, Yahoo and others fell prey to router incidents and accidents

By Carolyn Duffy Marsan, Network World, 01/15/2009

Share/Email | Buzz up! | 1 Comment | Print | **Toolshed - IT A&A**

Here's our list of the biggest security incidents involving the Internet's core routing protocol, the Border Gateway Protocol. Some of these incidents were attacks; others were accidental misconfigurations. But all of them disrupted traffic to Web sites or entire networks because of incorrect routing messages being propagated across the Internet through BGP. (Read the latest on [U.S. government efforts to secure BGP](#), and about [four open source BGP tools](#).)

### Pakistan Telecom blocks YouTube

In February 2008, [Pakistan Telecom](#) inadvertently [brought down](#) the entire [YouTube](#) site worldwide for two hours as it was attempting to restrict local access to the site. When Pakistan Telecom tried to filter access to YouTube, it sent new routing information via BGP to PCCW, an ISP in Hong Kong that propagated the false routing information across the Internet.

### ICANN puts root server at risk

The Internet Corporation for Assigned Names and Numbers (ICANN) [screwed up](#) in November 2007 when it renumbered the DNS root server "I" that it

## The Problem

- How do you check that use of Internet resources is legitimate?
  - “I’m multi-homed. Please advertise my /24”
  - “A spammer has hijacked 123.456.100.0/23. Please null route them.”
  - “That’s funny, I didn’t think that YouTube was based in Pakistan... Should AS123 be allowed to advertise their prefix?”
  - ...

# Address and Routing Security

- The (very) basic routing security questions that need to be answered are:
  - Is this a valid address prefix?

## Valid:

That the prefix has been allocated through the address distribution framework, and that this allocation sequence can be demonstrated and validated

# Address and Routing Security

- The (very) basic routing security questions that need to be answered are:
  - Is this a valid address prefix?
  - Who advertised this address prefix into the network?

## Who:

The route originator, identified by the origin AS of the corresponding route object. The originating AS also should be valid.

# Address and Routing Security

- The (very) basic routing security questions that need to be answered are:
  - Is this a valid address prefix?
  - Who advertised this address prefix into the network?
  - Did they have the necessary credentials to advertise this address prefix?

## Credentials:

Can a link be established between the address holder and the route originator such that the address holder has explicitly authorized the originating AS?

# Address and Routing Security

- The (very) basic routing security questions that need to be answered are:
  - Is this a **valid** address prefix?
  - **Who** advertised this address prefix into the network?
  - Did they have the necessary **credentials** to advertise this address prefix?
  - Is the advertised **path authentic**?

## An **authentic path**:

A sequence of valid ASs that represents a transit path from the current location to the prefix **and/or** A sequence of valid ASs that represents the path of the routing update message

# RESOURCE CERTIFICATION

## Resource Certificates

- X.509 certificates with IP Address and AS Number extensions (RFC3779)
- This changes the semantics of a certificate from the conventional notion of an identifying document (such as a passport) into a rights holder (such as a bearer bond)

## A Resource Certificate

- The holder of the corresponding private key has a right-of-use over the resources listed in this certificate
- CA Certificate:
  - The right-of-use holder can issue subordinate certificates (i.e. act as a local number registry and issue right-of-use certificates)
- EE Certificate
  - The right-of-use holder can generate digital signatures but cannot issue subordinate certificates (i.e. end user)

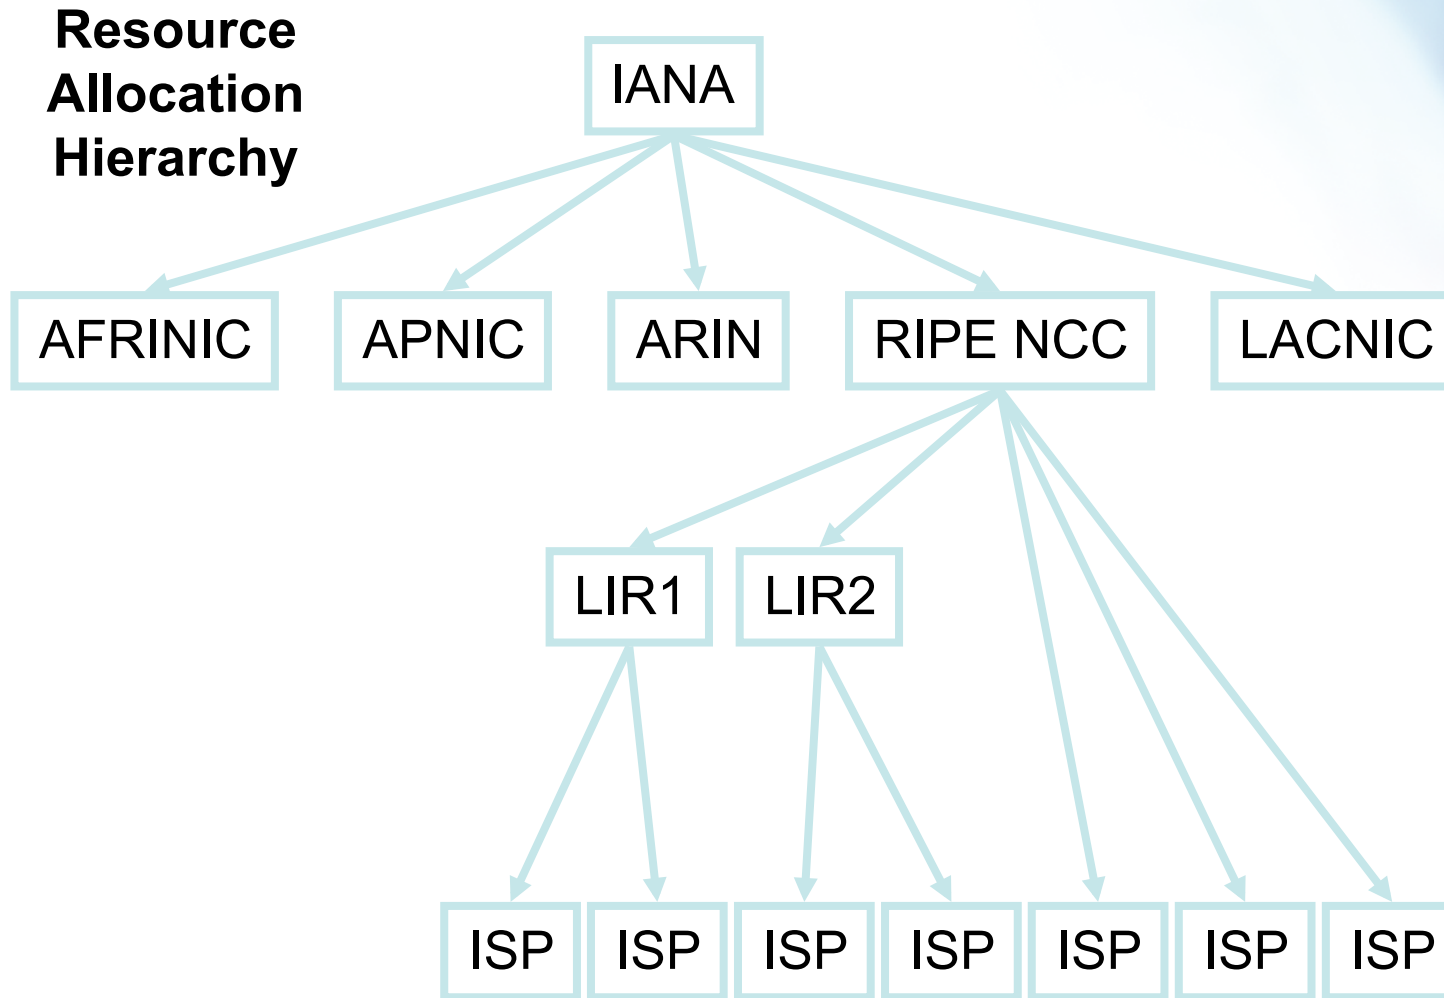

## Validating Resource Certificates

- Same validation task as conventional certificates, with one additional validation check:
  - The resources listed in a certificate must be a subset of the resources listed in the certificate referenced in the certificate's AIA field
- Change in validation semantics
  - From: Is this the key of the entity named "X"
  - To: Is this the key of the entity who holds the current right-of-use for IP address "X"

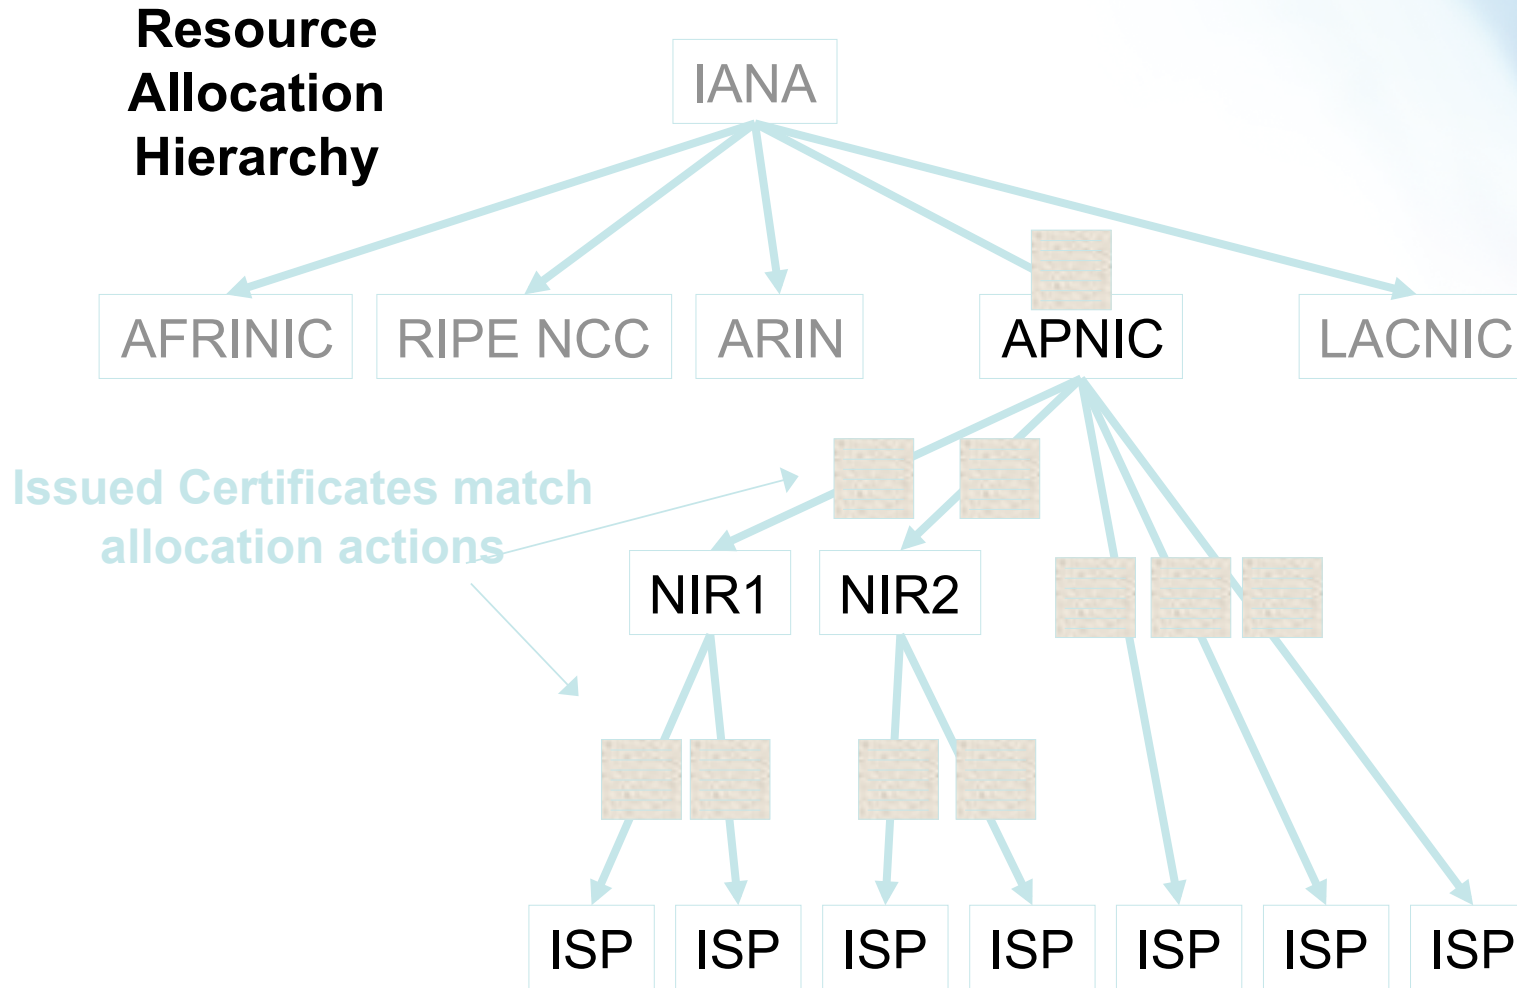

## Resource Certificate PKI

- Intended for Public Use IP resources
- Hierarchical PKI
- Precisely follows the resource allocation framework
  - Each registry in the allocation hierarchy is a CA
  - Each resource allocation is described in a Resource Certificate
- Trust Anchor is under discussion
  - Relying party to choose

# Resource Certificates

# Resource Certificates

# Resource Certificates

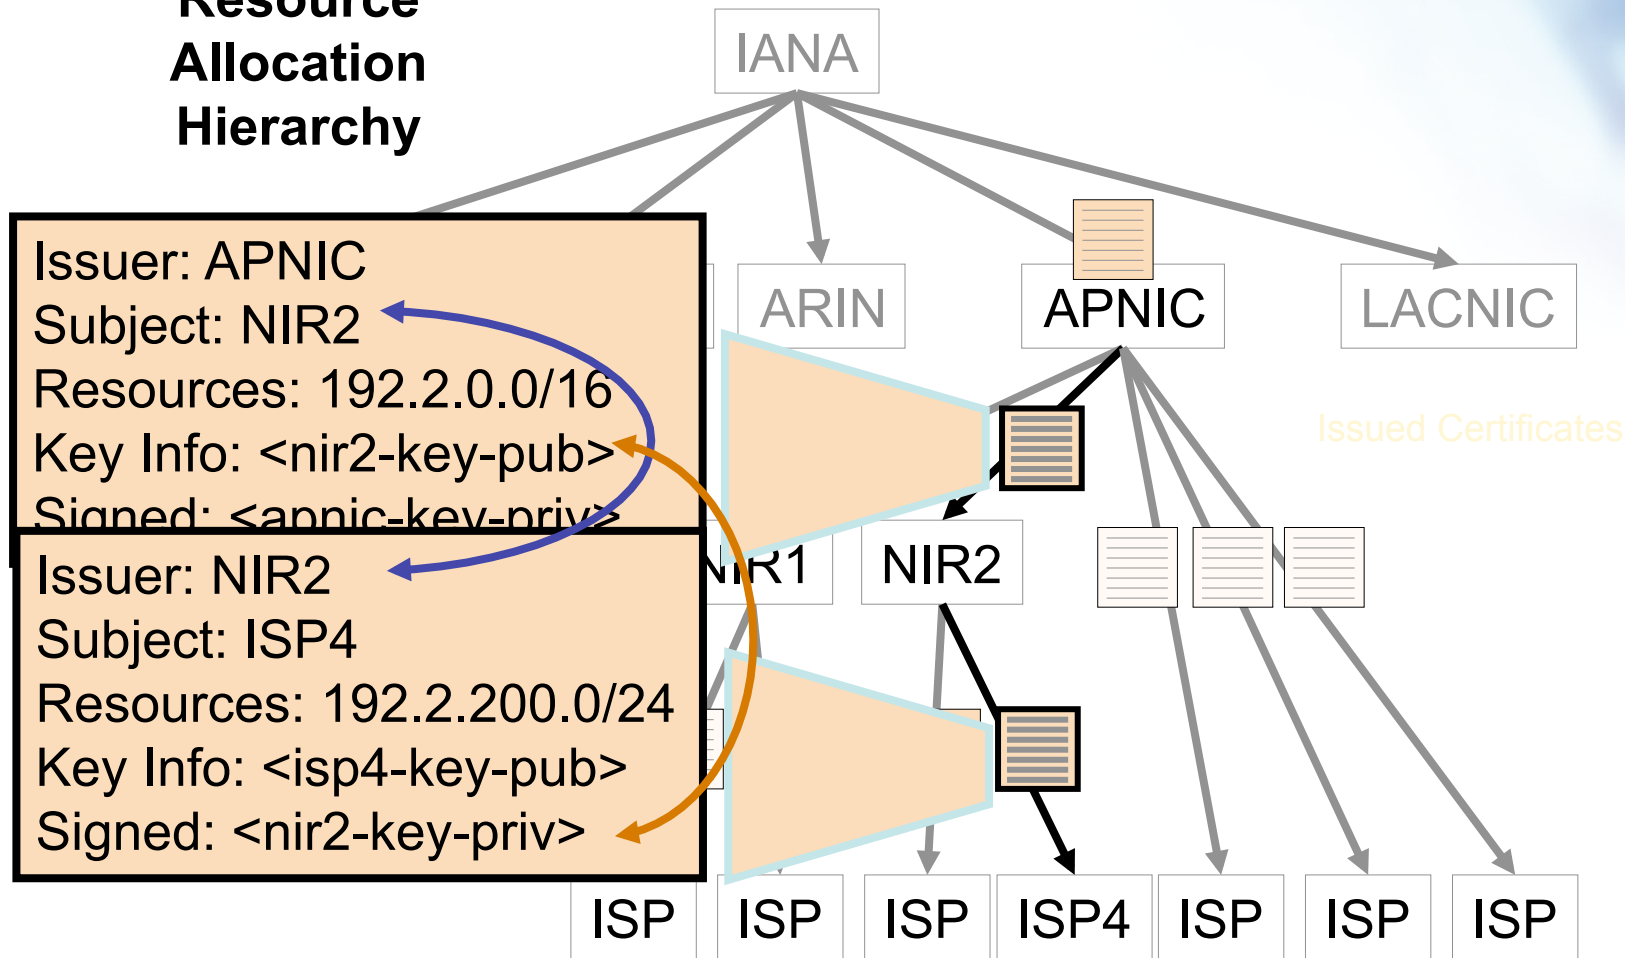

## Resource Allocation Hierarchy

# Resource Certificates

# Resource Certificates

## Resource Allocation Hierarchy

## Potential Uses of Resource Certificates

- Securing Whois objects
- Securing Internet Routing Registry objects
- Secure Routing
- Facilitating Resource Transfer functions
- Source address validation mechanism

# HOW RESOURCE CERTIFICATES CAN BE USED TO SECURE ROUTING

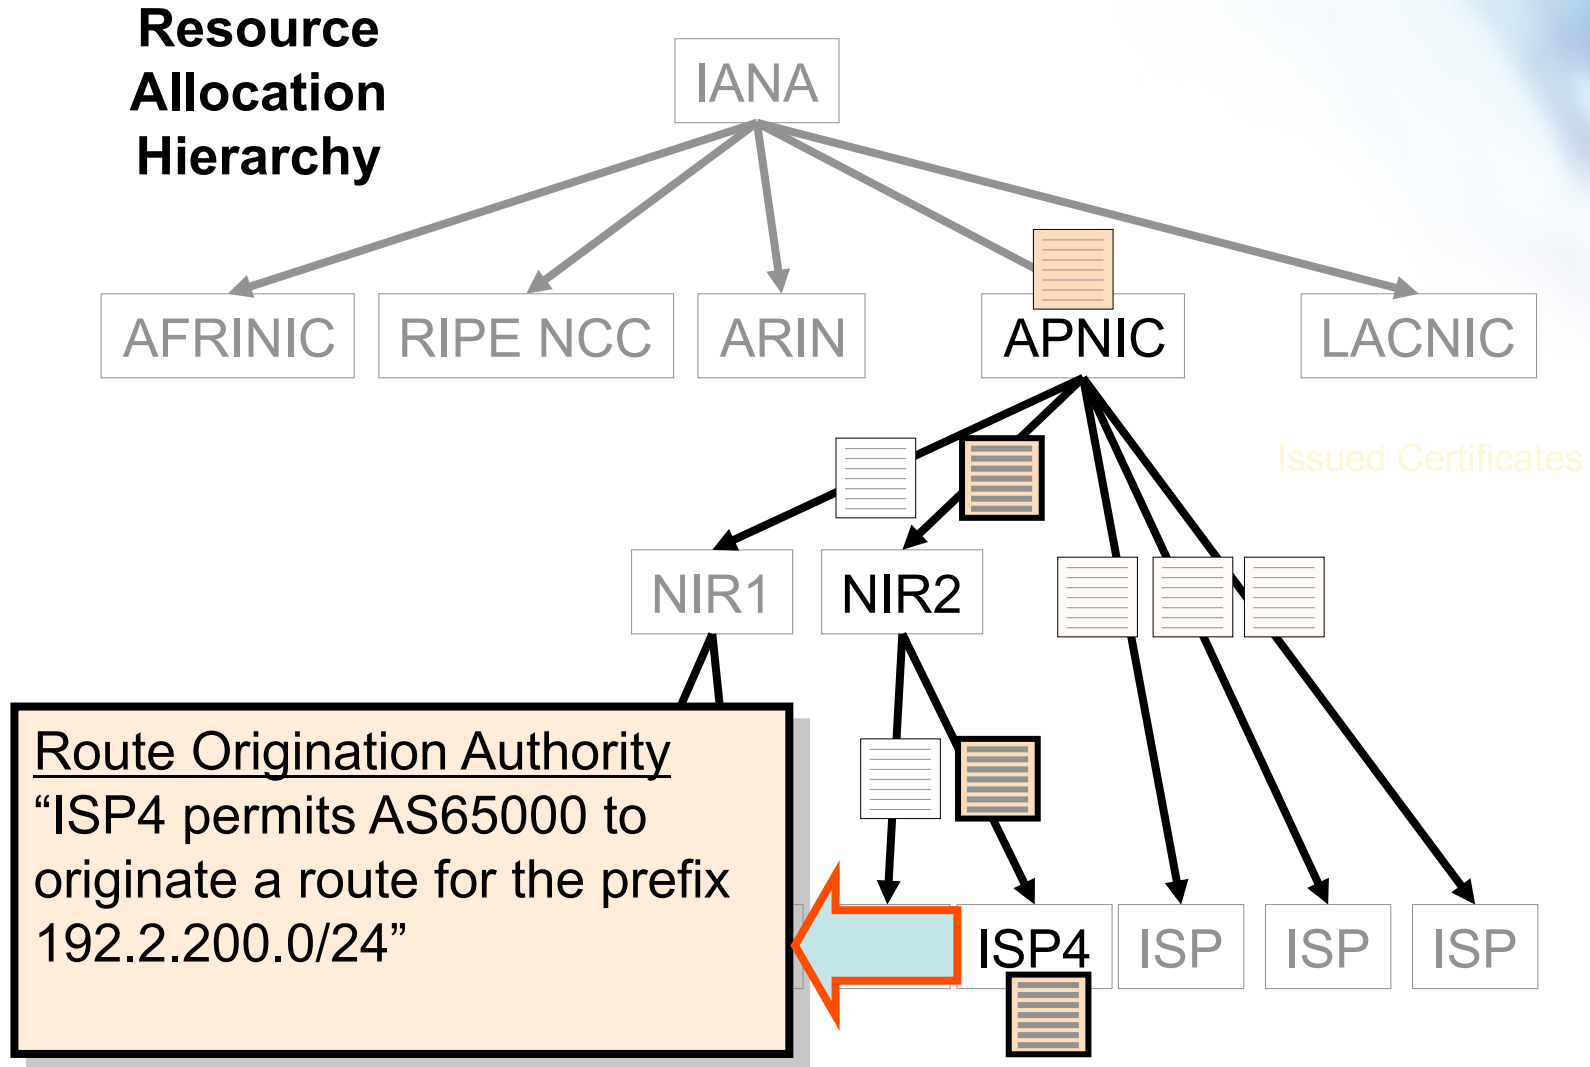

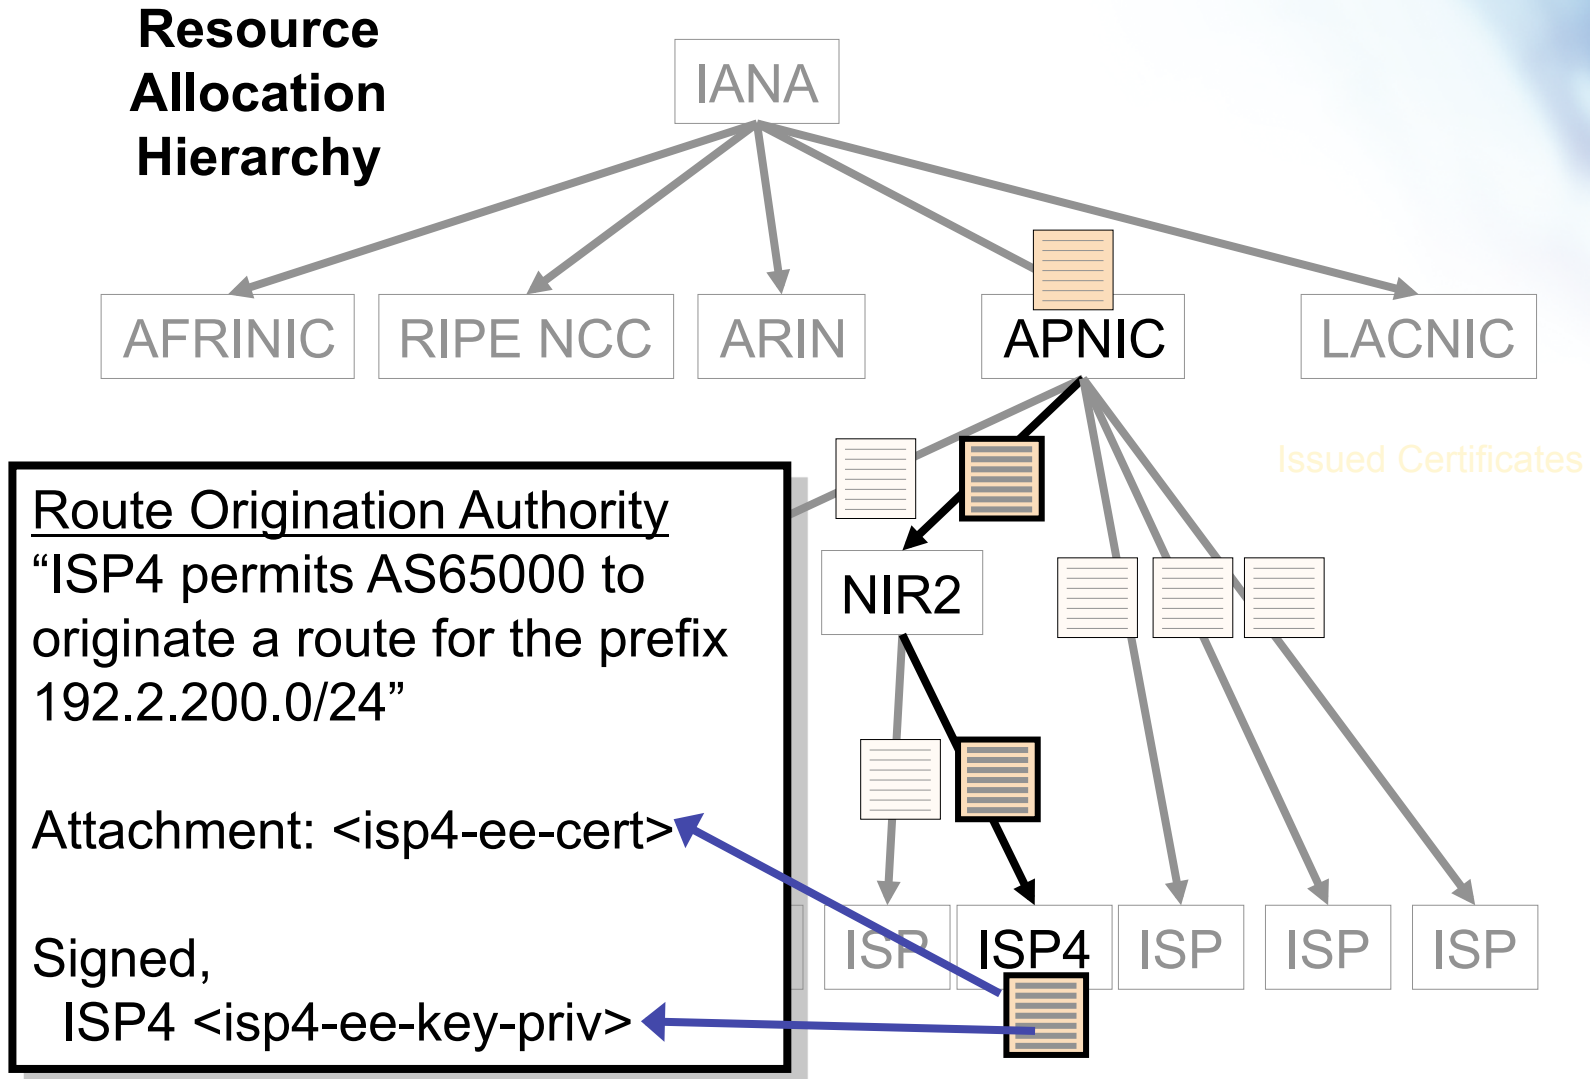

## Use it to sign routing attestations

- **Route Origin Authorizations (ROA)**
  - “I allow AS123 to announce prefix 10.0.0.0/8”, signed the holder of 10.0.0.0/8
- **Bogon Origin Attestation (BOA)**
  - “I attest that 10.10.10.0/24 and AS456 should never be announced”, signed the holder of 10.10.10.0/24 and AS456
- **AS Adjacency Attestation Objects (AAO)**
  - “I attest that AS456 is adjacent to AS123 and AS789”, signed the holder of AS456
- **Other signed data**

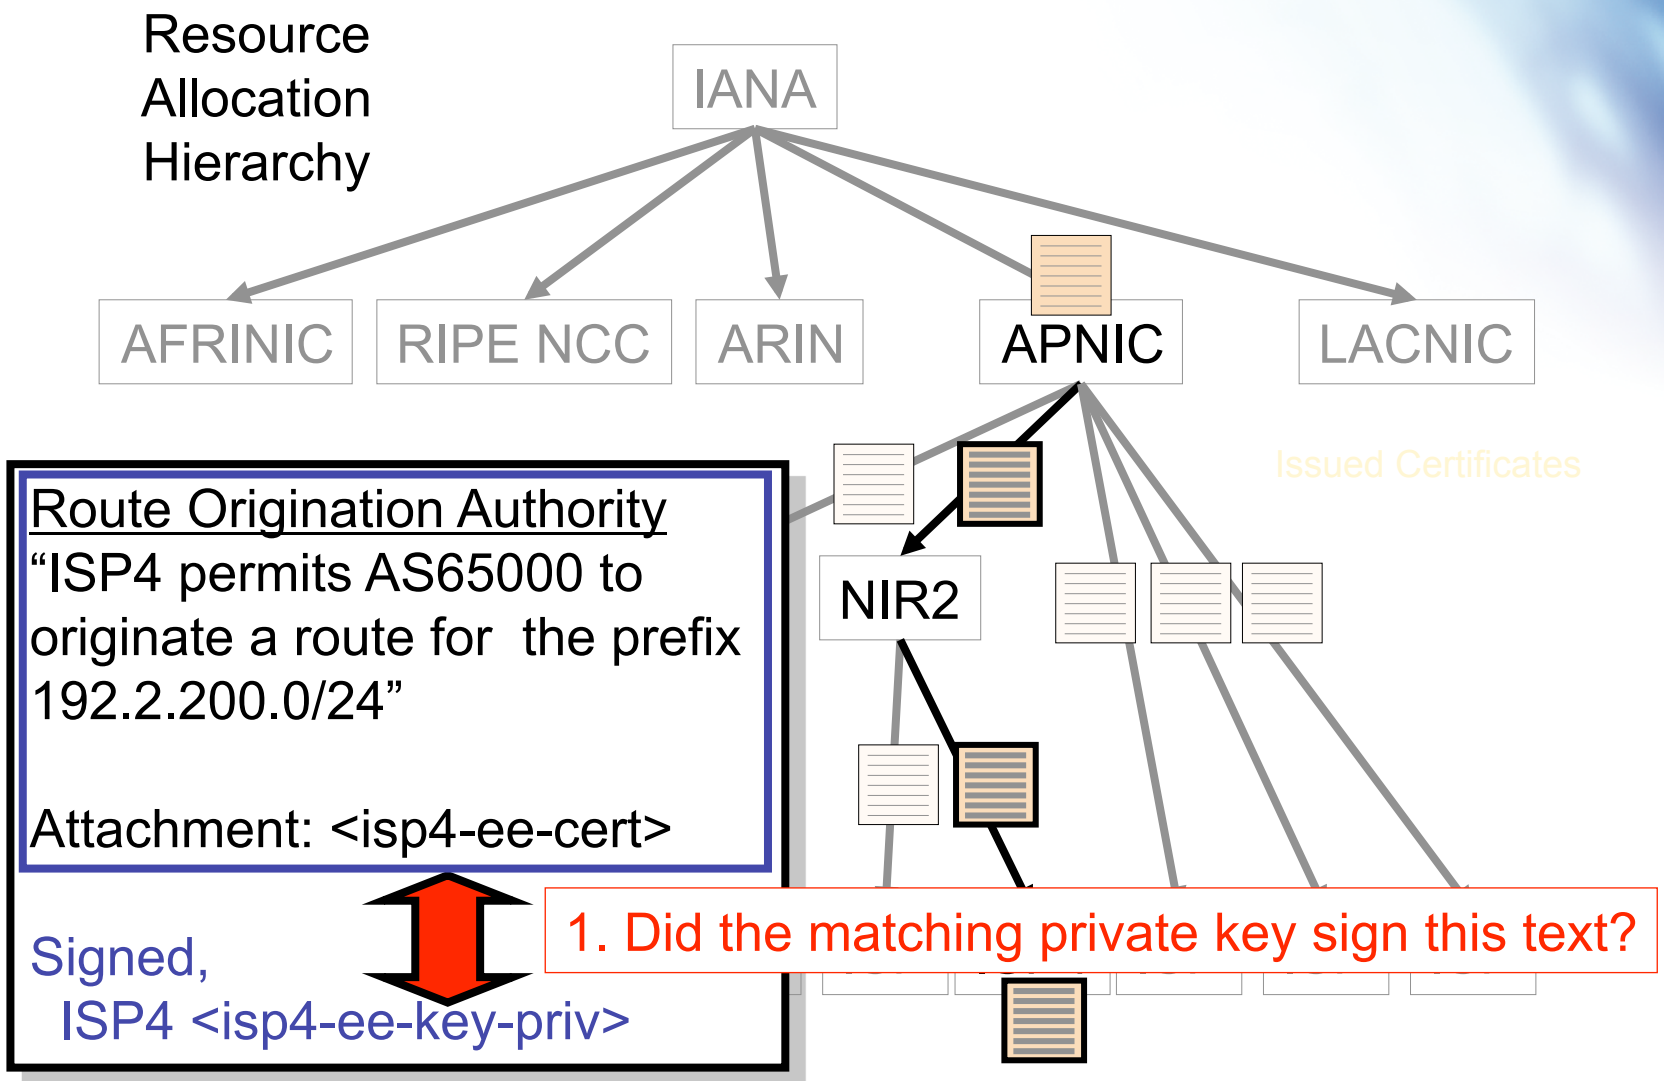

# Route Origination Authority document

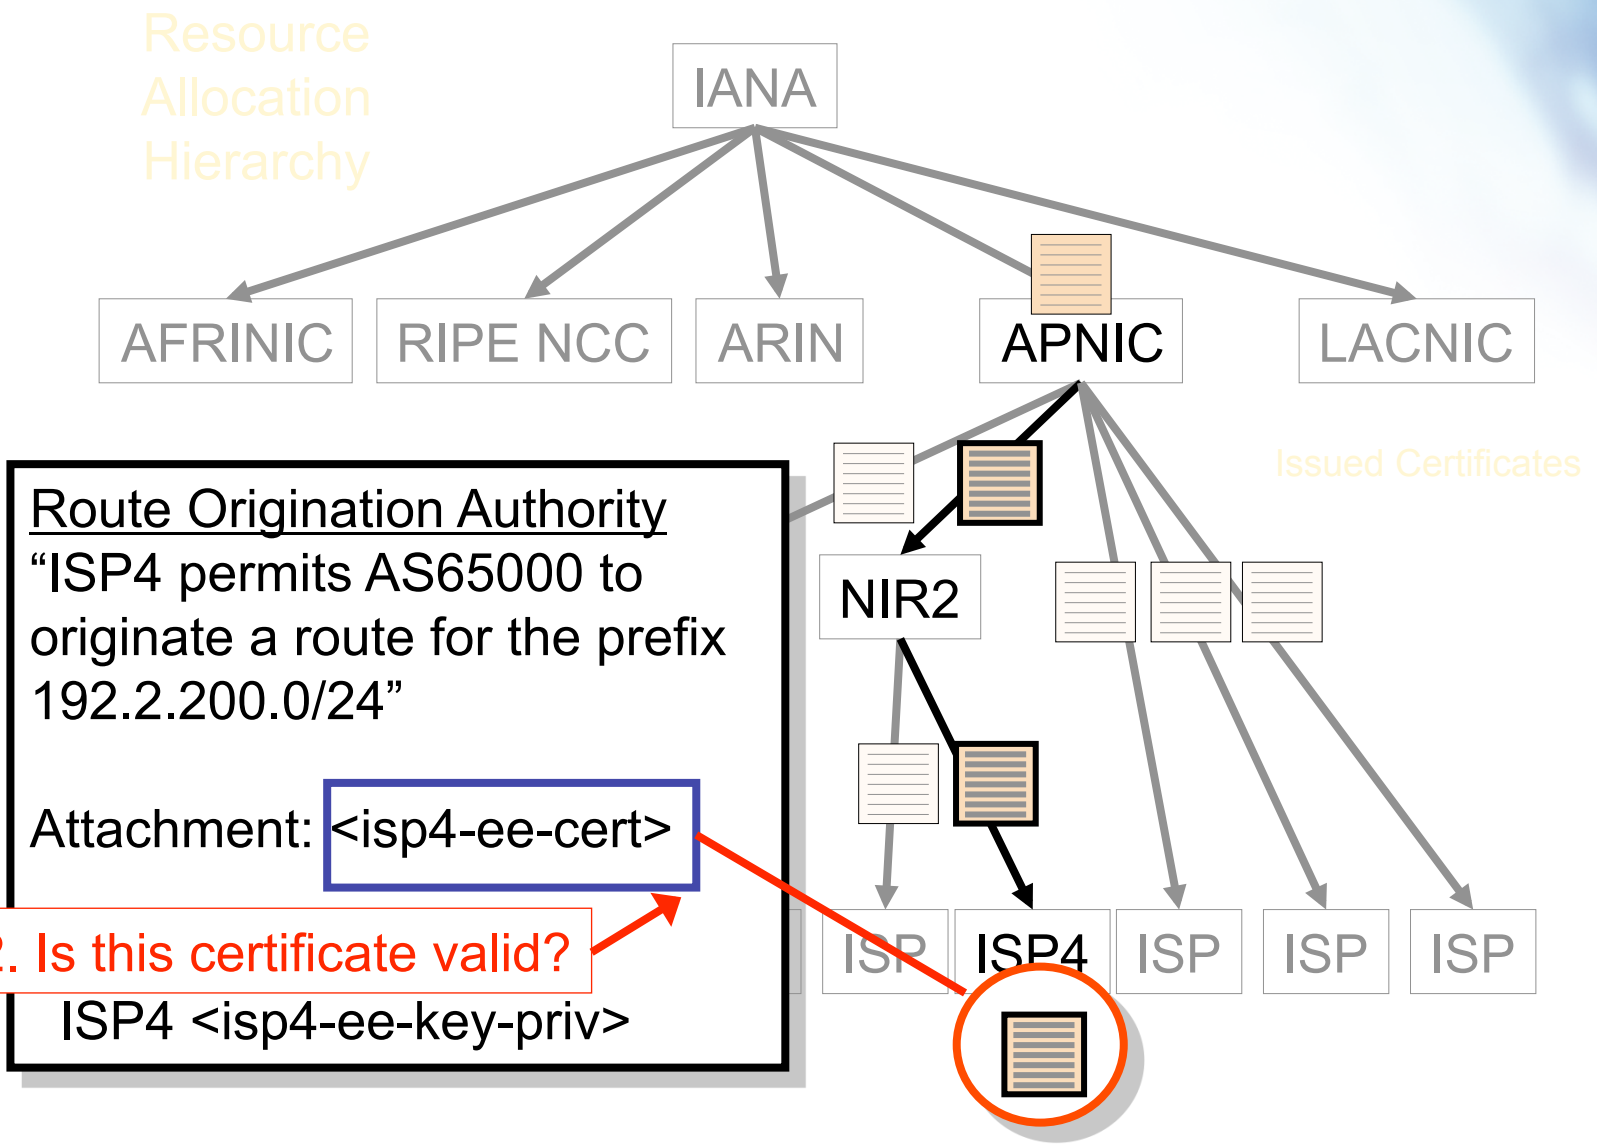

# Signed Objects

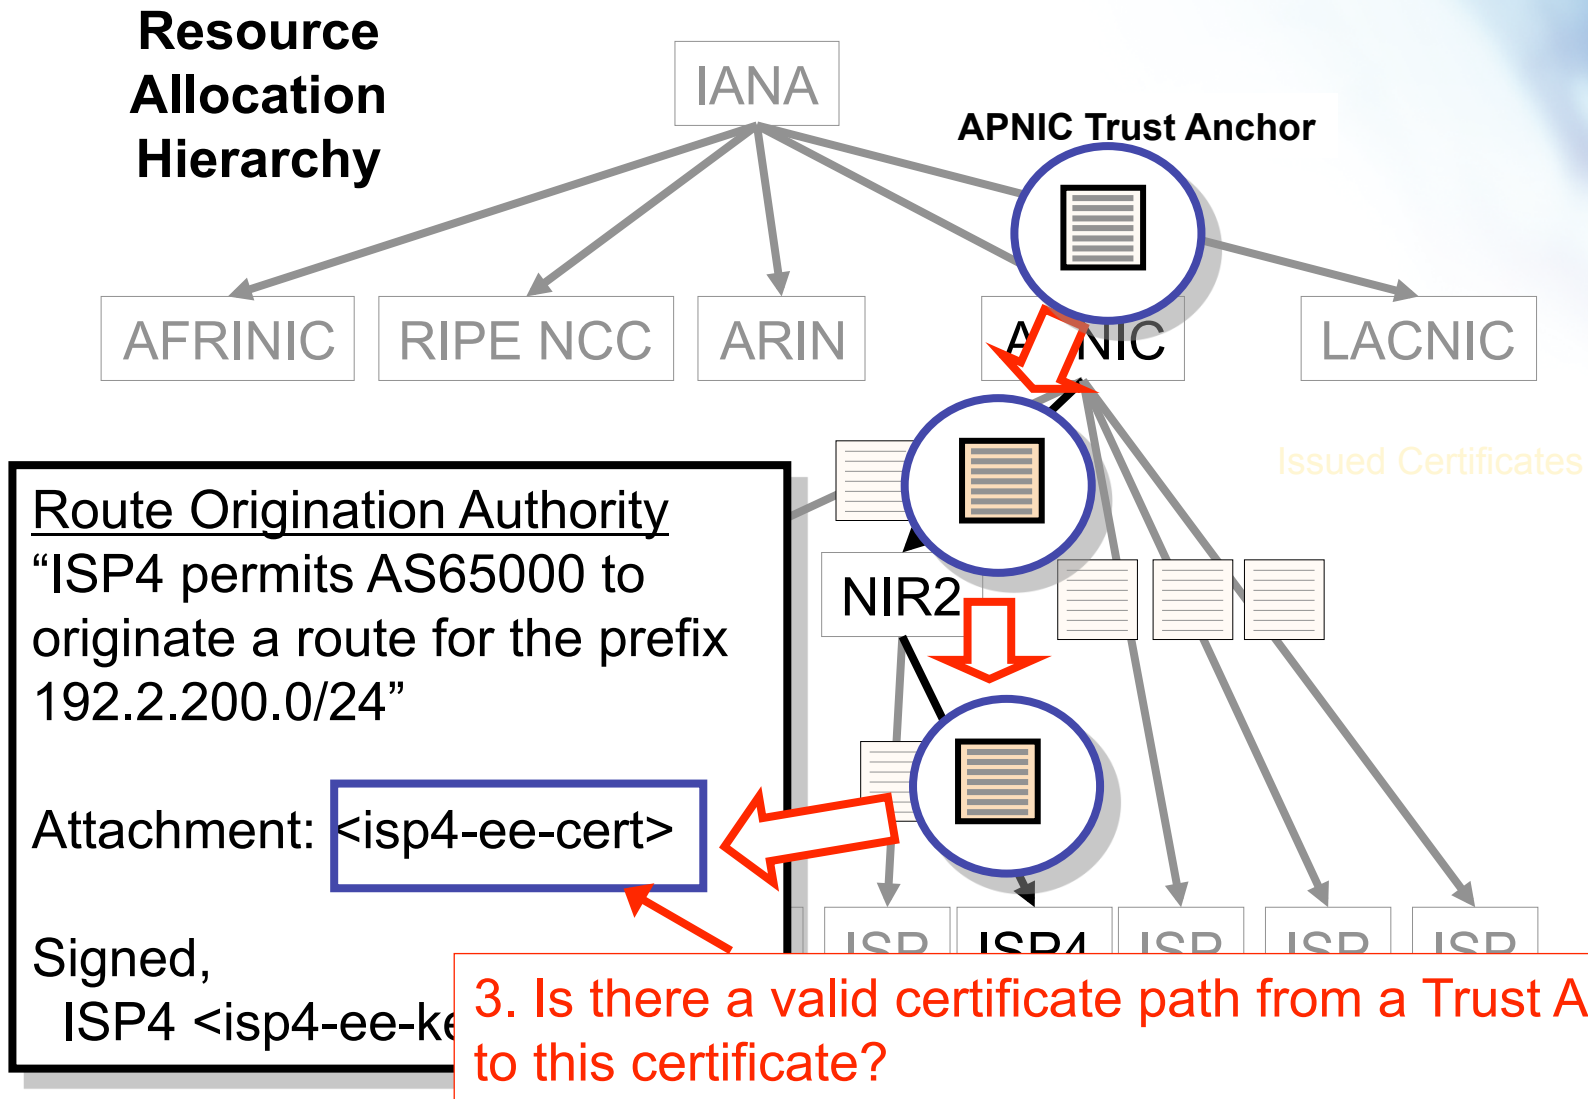

# Signed Object Validation

# Signed Object Validation

# Signed Object Validation

# Signed Object Validation

## Resource Allocation Hierarchy

## Route Origination Authority

“ISP4 permits AS65000 to originate a route for the prefix 192.2.200.0/24”

Attachment: <isp4-ee-cert>

Signed,  
ISP4 <isp4-ee-key-priv>

## Validation Outcomes

1. ISP4 authorized this Authority document
2. 192.2.200.0/24 is a **valid** address, derived from an APNIC allocation
3. ISP4 holds a current right-of-use of 192.2.200.0/24
4. A route object, where AS65000 originates an advertisement for the address prefix 192.2.200.0/24, has the explicit authority of ISP4, who is the current holder of this address prefix

## Conclusion

- Certification of IP Addresses and ASNs could help improve routing security by:
  - Mapping the delegation hierarchy to a Public Key Infrastructure hierarchy
  - Enabling routing instructions to be signed and validated by cryptographically secure processes.
